

ABSTRACT OF THE DISCLOSURE

When an information processing apparatus performs
the a process, it stores hysteresis data itemizing the a
process type, the an apparatus in charge of processing, a
a 5 person for instructing the process, the a process object
information and execution time. Then, necessary
hysteresis data are searched for by designating the
conditions in the items, desired hysteresis data is
selected from the hysteresis data that are found, and
10 the same process (re-printing of the same document) or
a new process (saving a printed document with a new
file name) is performed for the object in the selected
hysteresis data. The hysteresis number is provided for
the hysteresis data, and a correlation is provided for
15 the process that caused the process represented by the
hysteresis data, and the hysteresis number of the
process that is caused by the process represented by
the hysteresis data. When a specific hysteresis number
is designated for the search for the hysteresis data,
20 it is employed to acquire the hysteresis number for the
associated process, and the hysteresis data that has
the acquired hysteresis number is also added to be
object for a search.
